

Conclusions sur la détermination de la microfaune

The analysis of cores taken during the drilling operation of the Terebel's cruise in the northwestern Mediterranean Sea has put into evidence some reworked sediments. However, the occurrence of *Gtobigerina pachyderma*, *Gtoborotatia truncatutinoïdes* and *Hyalinea balthica* gives a quaternary age to these deposits (not older than Sicilian). The microfauna variations in some cores are related to paleoclimatological changes. Some of the sedimentary levels were deposited during a warming interglacial period. [NOT CONTROLLED OCR]
