

Age and growth analysis of the chub,

In this study, the population structure, growth parameters and condition of chub, *Squalius squalus*, from the Assino Creek, a tributary of the River Tiber, were investigated. A total of 1311 specimens were caught monthly from March 2008 to May 2009 by electrofishing. Total length ($TL \pm 0.1$ cm) and weight ($W \pm 0.1$ g) were recorded; age estimation was based on scalmometry and sex was determined by macroscopic observation of the gonads. Age composition ranged from 0+ to 11+. Total length varied from a minimum of 4.1 cm to a maximum of 48.8 cm, for a weight of 0.5 g and 1233.0 g, respectively. Length-weight regression was $\log 10W = -2.201 + 3.127 \log 10TL$ for males and $\log 10W = -2.273 + 3.190 \log 10TL$ for females. Previous growth was determined with back-calculation from scale measurements using the non-linear Body Proportional Hypothesis. Theoretical length growth was estimated with von Bertalanffy's model. Condition was evaluated by relative weight. In Italy there are few available data about the biology of *Squalius squalus*: the aim of this study was therefore to fill this lack of information by investigating some important aspects of the growth of the population in Assino Creek.
